

Experiment Agent Flow

This diagram presents the implemented experiment from the perspective of its agents and supporting modules. Read it from top to bottom.

How to Read It

- **Phase A runs once per C program.** The Tester generates visible inputs, the deterministic engine preserves executable cases and requests replacements for failed slots. The Validator then reviews the complete batch and may ask the Tester to replace only specific cases before the suite is frozen.
- **Phase B runs once per program and prompt.** The Translator produces Rust, the Tester compares C and Rust, and the Validator permits repair only when a translation discrepancy is confirmed.
- **The Evaluator owns Judge execution.** Initial and final Judge results are observational and never return to the Translator.
- **Gray routing and execution boxes are deterministic.** Colored agent boxes identify where the configured LLM or an agent-specific operation participates.
